

A Independent AML cohort projected into the frozen scaffold

B External longitudinal trajectories in projected space

C External calibration of attractor displacement

D Calibration summary of replicated treatment-aware structure

EOI/REM remains near the DX attractor

External response-associated samples remain close to the discovery baseline.

Median μ -shift:
DX = 0.424
EOI/REM = 0.405

REL is more displaced than EOI/REM

External relapse samples occupy a more displaced position than EOI/REM samples.

Median μ -shift:
EOI/REM = 0.405
REL = 0.499

Residual-like states remain diffuse

EOI/REM samples do not collapse into a single tightly restored state.

Median σ eff:
DX = 0.761
EOI/REM = 0.827

True longitudinal calibration is present

The external cohort contains full DX→EOI/REM→REL trajectories.

Sample5 | Sample6

These summaries support directional calibration rather than exact parameter replication: the frozen scaffold preserves interpretable diagnosis-, response-, and relapse-associated structure in an independent pediatric AML cohort.
